

# XSPEC Tutorial and Statistics

Basic steps for X-ray spectral analysis

# XSPEC Tutorial and Statistics

## Basic steps for *X-ray spectral analysis*

Where can I find XSPEC?

- XSPEC is part of the NASA HEASoft software suite

<http://heasarc.nasa.gov/lheasoft/>

- You can download HEASoft here:

<http://heasarc.gsfc.nasa.gov/docs/software/lheasoft/download.html>

- It's free!

- Supported architectures:

- macOS/Mac OS X
- PC Linux – Ubuntu (or other Debian-based Linux)
- PC Linux – Fedora (or other RPM-based Linux)
- PC Cygwin

# Step 1: loading data and “setup” commands

xspec

```
xspec> data pn_25.grp
xspec> ignore bad
xspec> ignore **-0.3 7.2-**
xspec> cpd /xw
xspec> plot ldata
```

To change the plotting device

Energy: with “.”  
Otherwise: channels

For each source, four files are needed:

- source spectrum
- background spectrum
- ARF matrix
- RMF matrix

grppha (see below) allows you to associate all these files before loading within xspec

To associate a source spectrum with its background file and response matrices (RMF and ARF) and to group it with a binning of e.g. 25 counts/bin, you can use (before loading the spectrum in XSPEC) the following ftool *grppha* and syntax:

```
grppha pn.pi pn_25.grp comm="group min 25 & chkey BACKFILE back_spectrum.fits & chkey ANCRFILE pn.arf & chkey RESPFIL pn.rmf & exit"
```

xspec> show all

XSPEC version: 12.8.2  
Build Date/Time: Thu Jul 10 09:26:57 2014

XSPEC12>data pn\_25.grp

Fraction of src counts/total

```
1 file 1 spectrum
Spectrum 1 Spectral Data File: pn_25.grp
Net count rate (cts/s) for Spectrum:1 2.652e+00 +/- 7.965e-03 (96.8 % total)
Assigned to Data Group 1 and Plot Group 1
Noticed Channels: 23-1321
Telescope: XMM Instrument: EPN Channel Type: PI
Exposure Time: 4.441e+04 sec
Using fit statistic: chi
Using test statistic: chi
Using Background File back_spectrum.fits
Background Exposure Time: 4.441e+04 sec
Using Response (RMF) File pn.rmf for Source 1
Using Auxiliary Response (ARF) File pn.arf

Spectral data counts: 121704
```

loaded bkg  
and response  
files

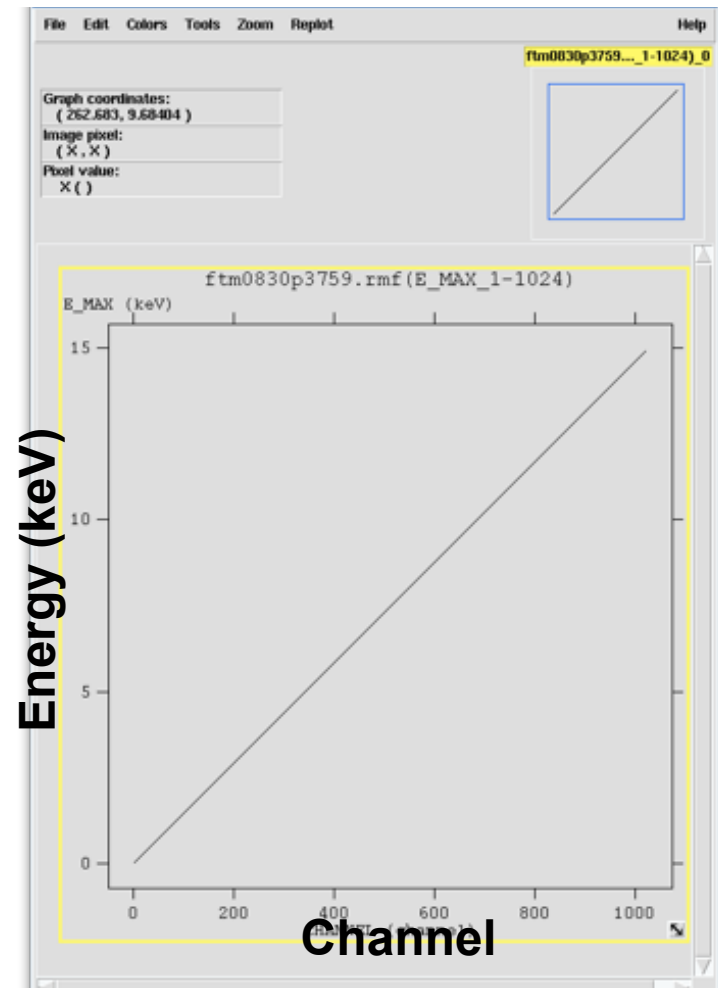

$$\text{Source net (i.e. background-subtracted) counts} = \text{data counts} \times \text{fraction} = 121704 \times 0.968$$

**Spectral binning choice:** (A) to have enough counts in each bin to apply  $X^2$  statistics; (B) the spectral bins should be independent (i.e., should match with the spectral resolution). Example: 5 spectral bins for each energy resolution bin (~100 eV for CCDs), each one meant as a Gaussian

# Step 1a: response matrices

**RMF**: links the instrumental channel scale with the physical energy (wavelength) scale

	1E	1E	1E

Go to:   Edit cell: 0.42

xspec> setplot energy

Channel scale = instrument scale  
Energy scale = "physical" scale

xspec> setplot rebin 10 30

minimum significance

max number of bins

(just for plotting purposes)

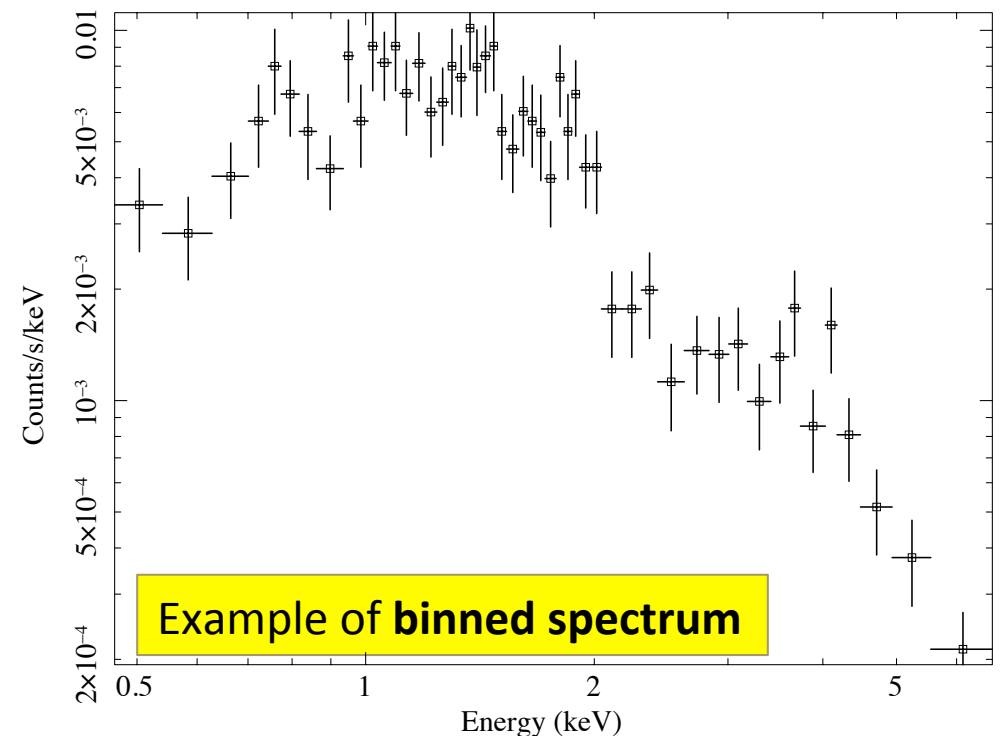

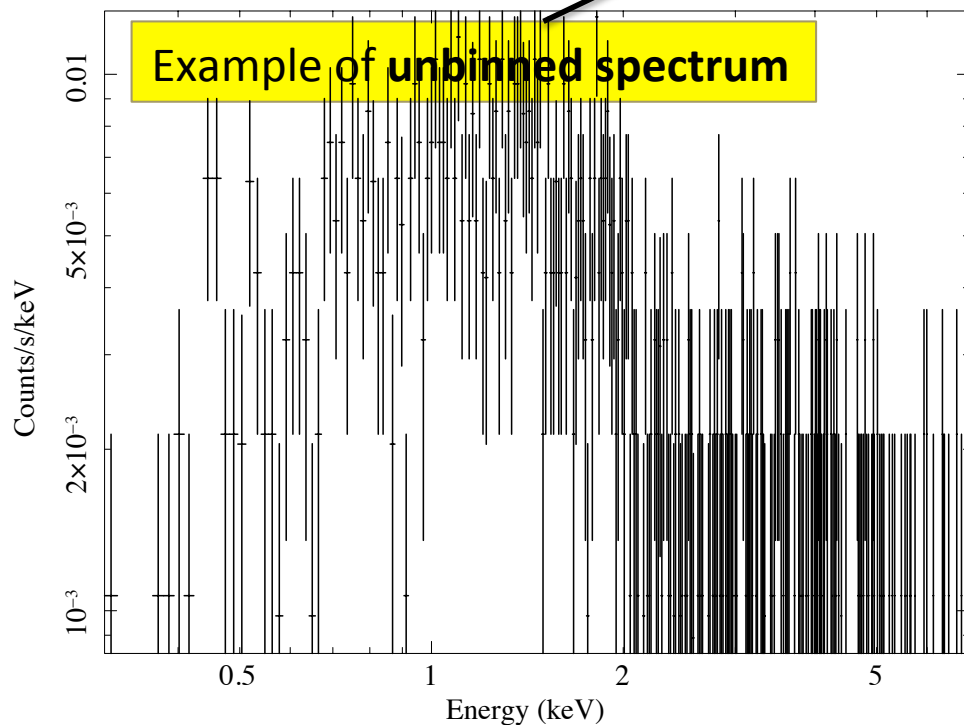

They are linked via the RMF (redistribution matrix file)

# Step 1b: what does 'binning' (grouping) mean?

To apply the  $\chi^2$  test, we need that in every bin we are in the Gaussian (or nearly Gaussian) regime, i.e., we have enough counts

With the tool *grppha* (or similar) we can require that each spectral bin contains at least a given number of counts

“original” distribution of the counts (note: here scale=energy)

Good photon statistics: it is suggested to rebin the data and apply  $\chi^2$

# Step 2: choice of the models

XSPEC models like math operations

## Additive models

## Multiplicative models

xspec> mo pha\*po

**pha**: accounts for the Galactic  $N_H$  (multiplicative model)  
**po**: powerlaw model (additive model)

It is possible to provide values to the parameters at every step of the fitting process

```
XSPEC12>mo pha*po
```

-1 means frozen parameter (the same as the command *freeze #* of the parameter; opposite: *thaw*)

Input parameter value, delta, min, bot, top, and max values for ...

1	0.001(	0.01)	0	0	100000	1e+06
1:phabs:nH>2.91e-1	-1					
1	0.01(	0.01)	-3	-2	9	10
2:powerlaw:PhoIndex>1.8						
1	0.01(	0.01)	0	0	1e+20	1e+24
3:powerlaw:norm>1e-6						

---

Model	Model Component	Parameter	Unit	Value	Active/On
1	1	phabs	nH	10^22	0.291000 frozen
2	2	powerlaw	PhoIndex	1.80000	+/- 0.0
3	2	powerlaw	norm	1.00000E-06	+/- 0.0

---

parameter number of  
number the component

```

xspec> query yes
xspec> renorm (to allow a preliminary "adjustment")
xspec> fit 100 (fit 100 times)

```

```

=====
Model phabs<1>*powerlaw<2> Source No.: 1 Active/On
Model Model Component Parameter Unit Value
par comp
  1 1 phabs nH 10^22 0.291000
  2 2 powerlaw PhoIndex 0.895250
  3 2 powerlaw norm 3.65973E-03
=====

```

```

Fit statistic : Chi-Squared =      10561.52 using 1299 PHA bins.
Test statistic : Chi-Squared =      10561.52 using 1299 PHA bins.
Reduced chi-squared =      8.143041 for 1297 degrees of freedom
Null hypothesis probability = 0.000000e+00

```

**dof=degrees of freedom=number of datapoints – number of free parameters=**  
**=1299-2=1297**

$\chi^2/\text{dof}$  close to unity means that it is a good fit (not in this case!)

Null hypothesis probability=probability that the model is a good representation of the datapoints (if close to 1)

**All the adopted models should be physically motivated according to the known source properties (or classification, or from data at other  $\lambda$ )**

# Step 3a: adding components

xspec> `addcomp 2 zpha` adding zpha as # component (#=order in the model)

```
XSPEC12>addcomp 2 zpha
```

Input parameter value, delta, min, bot, top, and max values for ...

3	2	zphabs	Redshift		4.80000E-02	frozen
4	3	powerlaw	PhoIndex		0.895250	+/- 4.39599E-03
5	3	powerlaw	norm		3.65973E-03	+/- 1.85394E-05

xspec> plot ldata delchi

xspec> plot model

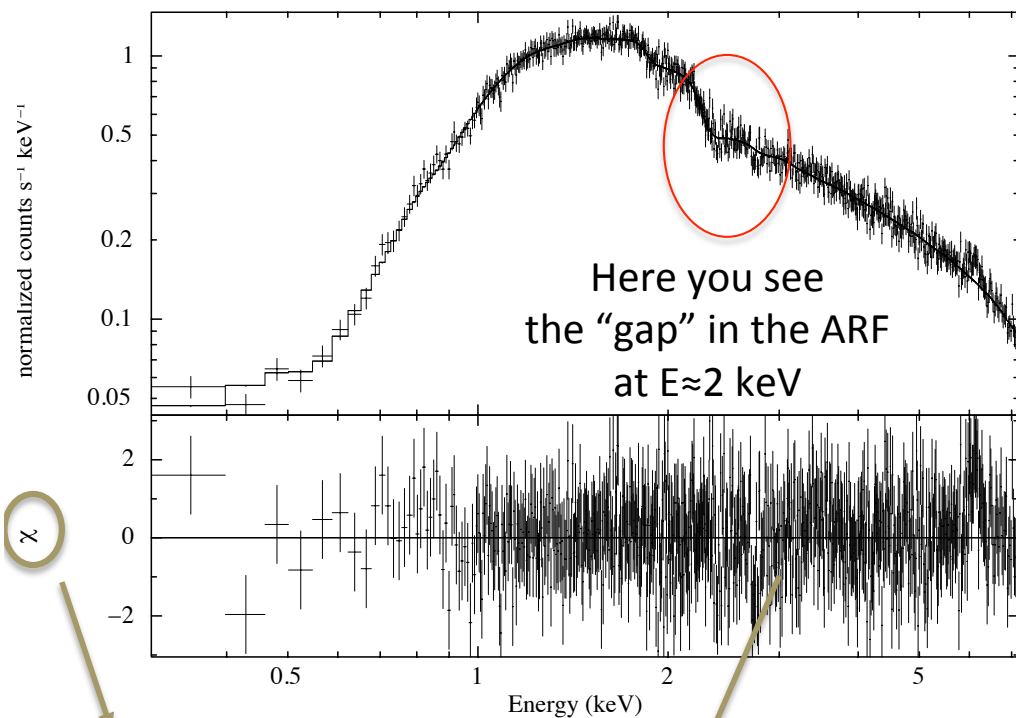

to plot the input model

xspec> plot eeufspec delchi

Convolved with the response matrix

eeufspec: unfolded spectrum in  $E^2 F(E)$

data and folded model

Here you see the "gap" in the ARF at  $E \approx 2$  keV

delchi: model-data deviations (in units of  $\sigma$ )

Unfolded Spectrum

## Step 4: statistical test: $\chi^2$

Test to compare the observed distribution of the results with that expected

$$\chi^2 = \sum_{k=1}^n \frac{(O_k - E_k)^2}{\sigma_k^2}$$

$O_k$ =observed values (spectral datapoints)

$E_k$ =expected values (model)

$\sigma_k$ =error on the measured values (error on each spectral bin)

$k$ =number of datapoints (bins after rebinning)

$$\chi^2 / dof \approx 1$$

the observed and expected distributions are similar

# Applicability of $\chi^2$ statistics

$$S = \sum_i \left( \frac{S_i - B_i t_s / t_b - m_i t_s}{\sigma_k} \right)^2 / \left( \frac{(\sigma_S)_i^2 + (\sigma_B)_i^2}{\sigma_k} \right)$$

$\chi^2$  statistic

where  $S_i$  = src counts in the  $I=\{1, \dots, N\}$  data bins with exposure  $t_s$ ,  
 $B_i$  = background counts with exposure  $t_b$  and  $m_i$  = model predicted  
count rate;  $(\sigma_S)^2$  and  $(\sigma_B)^2$  = variance on the src and background  
counts, typically estimated by  $S_i$  and  $B_i$

**BUT**

the  $\chi^2$  statistic fails in low-counting regime  
(few counts in each data bin)

# Alternative solutions in case of low photon statistics

- i. To rebin the data so that each bin contains a large enough number of counts

BUT: loss of information and dependence on the rebinning method adopted

- ii. To modify  $S$  so that it performs better in low-count regime (e.g., by estimating the variance for a given data bin using the average counts from the surrounding bins; Churazov+96)

BUT: it would need Monte Carlo simulations to properly support the result

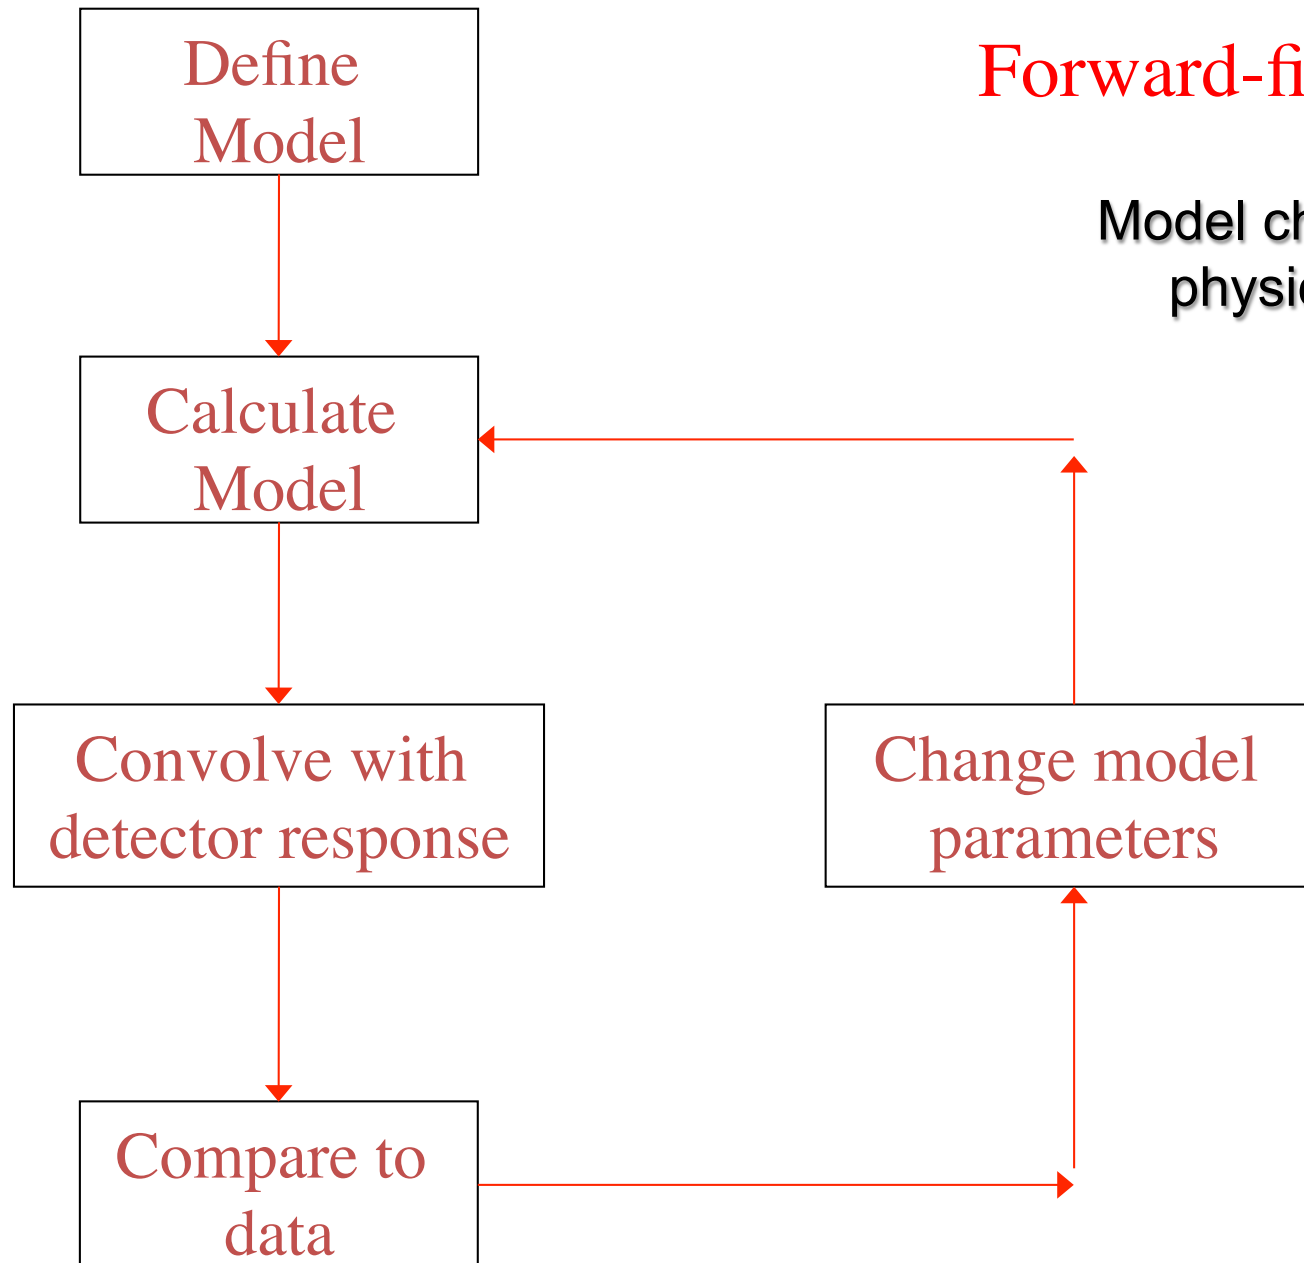

- iii. To construct a **maximum-likelihood estimator** based on the Poisson distribution of the detected counts (Cash79; Wachter+79). ML means finding the best fit of parameters that maximizes the Poisson likelihood

```
xspec> statistic chi (default)  
xspec> statistic cstat
```

Binned data,  $\chi^2$  statistics  $\Leftrightarrow$  Gaussian statistics  
Unbinned data, C-statistics  $\Leftrightarrow$  Poisson statistics

# Forward-fitting algorithm

Model choice based on the physics of the source

# Global vs. local minimum

*Data analysis*

If the fit process is started at the “right place”, then it will converge to the true minimum

The more complicated the model and the more highly correlated the parameters, then the more likely that the algorithm will hardly find the true minimum

xspec> `newpar 2 1.8`

to assign a new value to a parameter (2 here)  
(useful also to move from a local minimum...)

## $\chi^2$ in a nutshell

Reduced  $\chi^2$  large  $\leftrightarrow$   $P(\chi^2)$  small

- a. Errors are under-estimated
- b. The model does not describe the data well

Reduced  $\chi^2$  small  $\leftrightarrow$   $P(\chi^2)$  large

- c. Errors are over-estimated
- d. Data selected in a particular way?

# Step 5: error estimate

xspect> error #  
 (#=number of the parameter)

p	$\nu$					
	1	2	3	4	5	6
68.3%	1.00	2.30	3.53	4.72	5.89	7.04

1320.6	33.752	4	1.59	1	0.437
1309.1	22.255	3	1.58	1	0.437
1304.2	17.383	2	1.57	1	0.437
1306	19.155	1	1.56	1	0.437

Parameters involved in the fit

It provides how one parameter varies wrt. another (i.e. the error range for sets of parameters)

xspec> plot contours

90% c.l.: the photon index varies in the range 1.58–1.62 (vs. 1.58–1.61 using the *error* command). Slight differences are explained because in the case of the *error* command, the uncertainty was computed for one parameter of interest

## Step 6: source flux and luminosity

```
xspec> flux 2 10      (flux band in keV)
xspec> lum 2 10 0.048 (lum band redshift)
```

command *cosmo* to change the cosmology

```
XSPEC12> flux 2 10
Model Flux 0.0062186 photons (4.5024e-11 ergs/cm^2/s) range (2.0000 - 10.000 keV)
XSPEC12> ne 2 0

Fit statistic : Chi-Squared =      144391.0 using 1299 PHA bins.

Test statistic : Chi-Squared =      144391.0 using 1299 PHA bins.
Reduced chi-squared =      111.4128 for 1296 degrees of freedom
Null hypothesis probability = 0.000000e+00
Current data and model not fit yet.
XSPEC12> lum 2 10 0.048
Model Luminosity 2.4791e+44 ergs/s (2.0000 - 10.000 keV rest frame)
(z = 0.0480 H0 = 70.0 q0 = 0.00 Lambda0 = 0.730)
```

**Flux** is *observed* (typically, no correction for absorption) and in the observed-frame band (units: erg/cm<sup>2</sup>/s)

**Luminosity** needs to be intrinsic/de-absorbed (so, put  $N_H = 0$ ) and is reported in the source rest frame (units: erg/s)

# Step 7: the F-test

Model 1: absorbed powerlaw

Model 2: absorbed powerlaw + iron emission line

xspect> **addcomp 3 zgauss**

xspect> **fit 100**

```
XSPEC12>addcomp 3 zgauss
```

```
Input parameter value, delta, min, bot, top, and max values for ...
```

```

6.5      0.05(  0.065)      0      0      1e+06      1e+06
4:zgauss:LineE>6.4
0.1      0.05(  0.001)      0      0      10      20
5:zgauss:Sigma>.01 -1
0      -0.01(  0.01)      -0.999      -0.999      10      10
6:zgauss:Redshift>.048

8	4	powerlaw	PhoIndex		1.61154	+/- 9.66835E-03
9	4	powerlaw	norm		1.01037E-02	+/- 1.23074E-04

```
Fit statistic : Chi-Squared =      1253.29 using 1299 PHA bins.
```

```

Test statistic : Chi-Squared =      1253.29 using 1299 PHA bins.
Reduced chi-squared =      0.968541 for 1294 degrees of freedom
Null hypothesis probability =      7.868667e-01

```

$$\Delta\chi^2/\Delta\text{dof}=33.5/2$$

$\chi^2/\text{dof}=1253.3/1294$   
vs. 1286.8/1296 (no line)

```
xspec> ftest chi2_mod2 dof_mod2 chi2_mod1 dof_mod1
```

→ Low F value: low statistical significance of the added component

```
xspec> ftest 1253.3 1294 1286.8 1296
```

```
XSPEC12>ftest 1253.3 1294 1286.8 1296
```

```
F statistic value = 17.2939 and probability 3.87222e-08
```

Large F value=low probability  
= significant improvement due to  
the additional component

Use the F-test to evaluate the improvement to a spectral fit due to the assumption of a different model, with additional terms

Conditions: (a) the simpler model is nested within the more complex model;  
(b) the extra parameters have Gaussian distribution (not truncated by the parameter space boundaries) – BUT see also Protassov+02 on caveats

$$P_f(f; \nu_1, \nu_2) = \frac{\chi_1^2 / \nu_1}{\chi_2^2 / \nu_2}$$

$$\propto \Delta \chi^2 / k$$

The larger this ratio is,  
the larger the improvement  
is in the spectral fitting  
k=number of additional  
parameters

# Other useful commands

## in **XSPEC**

- `setplot rebin #1 #2` (to rebin the data; #1 indicates the number of  $\sigma$ )
- `show all`
- `show files`
- `show notice`
- `save all bestfit` (save the best fit model with the data in the file `bestfit.xcm`)
- `@bestfit.xcm` (to recall that particular model+data)
- `save model bestmodel.xcm` (save only the best fit model, without the data)

## In **ILOT**

`xspec> iplot`

- `time off` (to remove the date in the bottom-right part of the plot)
- `csize 2` (character size)
- `msize` (marker size)
- `label top` (title of the plot)
- `label filename` (title of the file)
- `hardcopy nomefile.ps/cps` (save a figure)
- `plot`
- `wen nomefile` (writes two files, one with data and the other with plot settings)
